ABSTRACT

Long-form live-streaming TTS requires context-dependent prosody and paragraph-level coherence. However, many existing instruction-based TTS systems use global or uniform conditions, providing limited explicit control over clause-level relative prosodic changes. We introduce Speaker-Relative Inline Prosody Control, where each Pitch, Energy, or Speed instruction targets a clause relative to the preceding clause from the same speaker, while Pause uses an absolute duration interval. In codec-based TTS, Speed and Pause affect sequence length, whereas Pitch and Energy rely on residual codebooks. By analyzing Qwen3-TTS RVQ codebooks, we find that Energy concentrates in early residual codebooks, whereas Pitch accumulates across a deeper prefix. We therefore propose Scope- and Codebook-Aware Instruction Conditioning (SCIC), combining a Temporal Instruction Router for frame-level tag activation with Tag-Specific Codebook Weighting over residual codebooks. SCIC improves speaker-relative Pitch and Energy control over standard instruction fine-tuning using text-token tags. We further apply multi-reward GDPO post-training to jointly optimize control and quality, improving control accuracy while preserving CER and speaker similarity. In long-form synthesis, SCIC produces a more distinct paragraph-level expressive hierarchy than speaker-adapted SFT without instructions. Audio demos are available at: <https://taoliveaigc.github.io/SCIC/>.

Index Terms— text-to-speech, speaker adaptation, relative prosody control, residual vector quantization

1. INTRODUCTION

In long-form live-streaming scenarios, speech exhibits local variations in pitch, energy, speaking rate, and pauses. TTS systems for this setting require fine-grained instruction control while maintaining paragraph-level coherence. Recent systems support natural-language instructions [1–11], categorical, continuous, or relative attribute control [12–14], and fine-grained local control through inline or hierarchical annotations [15–20]. Preference or policy optimization has also improved instruction adherence and controllability [8, 18]. However, existing methods do not jointly formulate inline prosody as a clause-level change relative to the preceding same-speaker clause and model its temporal scope and RVQ codebook allocation. This gap limits coherent prosodic progression in long-form synthesis.

We address this problem through Speaker-Relative Inline Prosody Control. An inline tag placed before a target clause specifies a local Pitch, Energy, Speed, or Pause change. For Pitch, Energy, and Speed, the preceding clause from the same speaker serves as

the reference anchor for the controlled clause; Pause is specified by an absolute duration interval. This formulation avoids imposing one absolute acoustic target across speakers and instead preserves speaker-specific prosodic variation. It also provides a direct interface for constructing paragraph-level expressive progression from a sequence of locally controlled clauses. Our setting is speaker-adapted rather than zero-shot speaker generalization: all controlled systems are adapted to the target voices during supervised fine-tuning and evaluated on held-out utterances from those speakers.

A remaining challenge is that different prosodic attributes are realized through different parts of a codec-based autoregressive generator. In Qwen3-TTS [21], the Main Talker predicts the first codebook q_0 and advances the acoustic-frame sequence, while Multi-Token Prediction (MTP) predicts residual codebooks q_1 – q_{15} within each frame. Speed and Pause primarily affect temporal progression and sequence length and can therefore be controlled through the existing q_0 path. Pitch and Energy, by contrast, depend on acoustic information distributed across the residual codebooks. Standard instruction fine-tuning represents inline tags only as text tokens and does not explicitly determine either when a Pitch/Energy tag should be active or how strongly it should affect each residual codebook.

To identify the relevant codec structure, we analyze Qwen3-TTS through RVQ Codebook Diagnosis, exchanging projected codebook contributions between original and attribute-transformed speech. The resulting cumulative-transfer trajectories differ substantially by attribute: Energy effects saturate within the first few residual codebooks, whereas Pitch transfer accumulates across a substantially deeper codebook prefix. Motivated by this observation, we propose Scope- and Codebook-Aware Instruction Conditioning (SCIC). Its Temporal Instruction Router predicts frame-level activation for each inline Pitch/Energy tag, and its Tag-Specific Codebook Weighting modulates the signed conditioning strength across q_1 – q_{15} . The two components jointly inject a localized SCIC conditioning signal into MTP, while Speed and Pause remain on the autoregressive q_0 path. We further post-train SCIC-SFT with multi-reward GDPO to jointly optimize prosody control, Pause accuracy, intelligibility, and speaker similarity. Experiments confirm improved local control while preserving synthesis quality and long-form coherence.

Our key contributions are as follows. First, we formulate Speaker-Relative Inline Prosody Control with absolute Pause intervals and relative Pitch, Energy, and Speed Up/Down instructions. Second, RVQ Codebook Diagnosis reveals attribute-dependent behavior: Energy transfer saturates within the first few residual codebooks, whereas Pitch transfer accumulates across a substantially deeper codebook prefix. Third, we propose SCIC, which combines a Temporal Instruction Router with Tag-Specific Codebook Weighting, and further improve SCIC-SFT through multi-reward GDPO post-training with explicit control and quality objectives.

2. METHODOLOGY

2.1. Overall framework

Figure 1 illustrates the generation pipeline. The Main Talker predicts q_0 and provides the frame-level state h_t to SCIC. For each Pitch/Energy tag τ , its tag embedding e_τ , presence indicator χ_τ , Router output $\rho_{t,\tau}$, and codebook weight $\omega_{\tau,k}$ form $s_{t,k}$ after summation over tags. At residual step k , this signal is added to the preceding codebook-token embedding, yielding $u_{t,k} = E_{k-1}(q_{t,k-1}) + s_{t,k}$. MTP uses h_t and the conditioned inputs to predict q_1 – q_{15} , whose projected contributions are summed and decoded. Multi-reward GDPO further optimizes control, intelligibility, and speaker similarity.

2.2. Speaker-relative inline control formulation

We first formalize how inline instructions specify local prosodic targets. Each instruction associates a target clause with either a speaker-relative change in Pitch, Energy, or Speed, measured against the immediately preceding clause from the same speaker, or an absolute Pause interval at the instructed boundary. Let c_{i-1} and c_i denote the reference and target clauses, respectively, with the inline tag placed immediately before c_i . For voiced-median pitch F_i , shared-voiced Top-80% RMS energy E_i , and aligned-character speaking rate r_i , the adjacent-clause changes are

$$\begin{aligned} \Delta_i^{\text{pit}} &= 12 \log_2(F_i/F_{i-1}), & \Delta_i^{\text{eng}} &= 20 \log_{10}(E_i/E_{i-1}), \\ \Delta_i^{\text{spd}} &= \log(r_i/r_{i-1}), & m_i^a &= \eta_i \Delta_i^a, \end{aligned} \quad (1)$$

where $a \in \{\text{pit}, \text{eng}, \text{spd}\}$ indexes the controlled attribute, and $\eta_i = +1$ for an Up instruction and -1 for a Down instruction. Thus m_i^a is the direction-normalized change, with a positive value always indicating movement in the requested direction. The logarithmic definitions provide symmetric representations of reciprocal Up and Down changes and avoid imposing one absolute acoustic target across speakers.

Pause is treated as an absolute-duration task with three reported levels: L1 [0.50, 0.75], L2 [0.75, 1.00], and L3 [1.00, 1.25] seconds.

2.3. RVQ codebook diagnosis

Given an original waveform x , we construct a duration-matched counterpart x' by applying either an upward or downward Pitch shift, or an increase or decrease in Energy. Codec encoding produces $C, C' \in \mathbb{Z}^{T \times 16}$, where T is the number of codec frames and column k contains codebook- k tokens. Let ℓ_k and ℓ'_k denote the projected contribution of codebook k to the decoder input, giving $z = \sum_{k=0}^{15} \ell_k$ and $z' = \sum_{k=0}^{15} \ell'_k$. We exchange these projected contributions rather than discrete token columns. For a codebook set $S \subseteq \{0, \dots, 15\}$,

$$\delta_S = \sum_{k \in S} (\ell'_k - \ell_k), \quad \tilde{z}_S^{\rightarrow} = z + \delta_S, \quad \tilde{z}_S^{\leftarrow} = z' - \delta_S. \quad (2)$$

Here δ_S is the transformed-minus-original contribution from S ; $\tilde{z}_S^{\rightarrow}$ inserts it into z , whereas $\tilde{z}_S^{\leftarrow}$ removes it from z' . Let D denote codec decoding and ϕ_a the measurement of attribute $a \in \{\text{pit}, \text{eng}\}$. Transfer relative to the complete codec-reconstructed change is

$$\begin{aligned} \text{Tr}_{S,a}^{\rightarrow} &= \frac{\phi_a(D(\tilde{z}_S^{\rightarrow})) - \phi_a(D(z))}{\phi_a(D(z')) - \phi_a(D(z))}, \\ \text{Tr}_{S,a}^{\leftarrow} &= \frac{\phi_a(D(z')) - \phi_a(D(\tilde{z}_S^{\leftarrow}))}{\phi_a(D(z')) - \phi_a(D(z))}. \end{aligned} \quad (3)$$

Forward intervention inserts the transformed contributions into the original reconstruction, while reverse intervention removes them from the transformed reconstruction. Negative transfer indicates movement opposite to the transformation, and values above 100% indicate overshoot. These ratios describe attribute transfer under latent intervention rather than additive information percentages.

Energy rapidly saturates within q_1 – q_3 , whereas Pitch requires a deeper interacting prefix and approaches saturation around q_1 – q_{10} . These different trajectories motivate tag-specific codebook weights rather than uniform injection or one fixed profile.

2.4. Scope- and codebook-aware instruction conditioning

SCIC factorizes local instruction conditioning along the temporal and codebook axes. Let τ index the four inline Pitch/Energy instruction-tag types, $\chi_\tau \in \{0, 1\}$ indicate whether tag τ occurs in the input, and $e_\tau = P_{\text{text}} \text{Emb}_{\text{text}}(\tau)$ be its projected text representation. Here $\text{Emb}_{\text{text}}(\tau)$ is the embedding of tag token τ , and P_{text} is the existing Qwen3-TTS text projection that maps it to the hidden dimension shared by the Main Talker and MTP inputs. Given the Main Talker state h_t associated with codec frame t , the Temporal Instruction Router predicts

$$\rho_{t,\tau} = \sigma([W \text{LN}(h_t) + b]_\tau) \chi_\tau. \quad (4)$$

Here W and b are learned Router parameters, LN is layer normalization, and σ is the logistic sigmoid. Thus $\rho_{t,\tau} \in [0, 1]$ specifies the frame-level activation strength of tag τ ; multiplication by χ_τ makes absent tags exactly inactive. Aligned clause spans provide binary frame-level supervision. The Router loss balances positive and negative frames separately for each supervised tag type so that long inactive regions do not dominate training.

For residual codebook $k \in \{1, \dots, 15\}$, Tag-Specific Codebook Weighting assigns each tag a zero-initialized parameter $\omega_{\tau,k}$. The localized conditioning signal and conditioned input are

$$\begin{aligned} s_{t,k} &= \sum_{\tau} \rho_{t,\tau} \omega_{\tau,k} e_\tau, \\ u_{t,k} &= \text{Emb}_{k-1}(q_{t,k-1}) + s_{t,k}. \end{aligned} \quad (5)$$

MTP predicts $(\hat{q}_{t,1}, \dots, \hat{q}_{t,15})$ from h_t and $(u_{t,1}, \dots, u_{t,15})$. Here Emb_{k-1} is the codec-token embedding used when predicting $q_{t,k}$. The Router controls temporal scope, while $\omega_{\tau,k}$ controls signed strength across q_1 – q_{15} . Pitch and Energy use this explicit SCIC conditioning path. Training combines generation and balanced frame-level Router losses, $\mathcal{L} = \mathcal{L}_{\text{gen}} + \lambda_r \mathcal{L}_{\text{router}}$, where λ_r weights the Router objective.

2.5. Multi-reward GDPO post-training

SCIC-SFT is post-trained with bounded control and quality rewards. For Pitch, Energy, or Speed, let m be the direction-normalized change, $T = T_{v,a} = 1.8\sigma_{v,a}$ the frozen speaker-specific threshold, and $P = P_{v,a,d}$ the direction-specific training-set 99th-percentile cap, with $0 < T < P$. The control reward is

$$R_{\text{ctrl}}(m) = \begin{cases} \max(-1, m/T), & m \leq 0, \\ m/T, & 0 < m < T, \\ 1, & T \leq m \leq P, \\ \max\left(-1, 1 - \frac{2(m-P)}{P-T}\right), & m > P. \end{cases} \quad (6)$$

Fig. 1. SCIC in Qwen3-TTS. The Main Talker predicts q_0 and provides h_t . For each Pitch/Energy tag, its tag embedding is scaled by the Temporal Instruction Router output and the tag-specific codebook weight to form $s_{t,k}$, which conditions MTP prediction of q_1 – q_{15} .

This rewards requested-direction changes above T and penalizes incorrect or excessive responses. For pause duration p and target interval $[l, h]$, let $\text{dist}(p, [l, h]) = \max(l - p, 0, p - h)$. The Pause reward is

$$R_{\text{pau}}(p) = \begin{cases} 1, & p \in [l, h], \\ \max\left(-1, 1 - \frac{2 \text{dist}(p, [l, h])}{h - l}\right), & \text{otherwise.} \end{cases} \quad (7)$$

Bounded CER and speaker-similarity rewards preserve intelligibility and speaker identity. Following GDPO [22], each objective o is standardized across the G responses j to input i before weighted aggregation:

$$A_o^{(i,j)} = \frac{R_o^{(i,j)} - \mu_{i,o}}{\sigma_{i,o} + \epsilon}, \quad A^{(i,j)} = \sum_o w_o A_o^{(i,j)}. \quad (8)$$

Here ϵ ensures numerical stability and w_o weights objective o , preventing reward-scale differences from dominating optimization.

3. EXPERIMENTS

3.1. Experimental setup

Dataset. Our supervised data comprise approximately 1,000 hours of natural Chinese speech from 30 speakers. Each recording is at most 90 seconds long, and the processed corpus contains 132,018 instruction tag. All evaluation utterances are disjoint from the supervised and post-training data.

Implementation details. We initialize all systems from a live-streaming Qwen3-TTS CPT checkpoint and then perform supervised fine-tuning on our instruction data. Instruction SFT uses

the same inline tags and supervised data but represents the instructions only through text-token conditioning. SCIC-SFT additionally introduces the Temporal Instruction Router and Tag-Specific Codebook Weighting, and SCIC-GDPO further applies multi-reward post-training. Supervised fine-tuning uses rank-32 LoRA [23] with $\alpha = 64$ on attention and MLP projections. AdamW uses learning rates of 10^{-5} for LoRA and 10^{-4} for control embeddings, the Router, and tag-specific codebook weights. We train on eight NVIDIA RTX PRO 5000 72GB GPUs with a per-GPU batch size of 8. SCIC-GDPO samples eight responses per input and uses a learning rate of 5×10^{-6} .

Evaluation metrics. We evaluate 1,800 Pitch/Energy/Speed samples using control-direction accuracy and median direction-normalized change, and 1,200 samples per Pause level using interval-hit accuracy. Qwen3-ForcedAligner-0.6B [24] provides alignment, Qwen3-ASR [24] measures CER on 1,800 texts, and WeSpeaker [25] measures similarity on 1,200 samples. Router localization is reported as mean aligned boundary error in milliseconds. Long-form HMOS uses 200 texts, outputs longer than 60 seconds, and five listeners.

3.2. Main results

Relative to Instruction SFT, SCIC-SFT improves Pitch, Energy, Speed, and Pause by 7.31, 10.53, 0.51, and 0.67 percentage points, respectively, with the largest gains on the explicitly conditioned Pitch and Energy attributes. Multi-reward post-training extends the corresponding SCIC-GDPO gains to 9.65, 11.30, 2.97, and 3.87 percentage points. CER remains within a narrow 1.63–1.68% range, while speaker similarity remains essentially unchanged.

Pause ACC measures whether the detected silence falls inside the requested duration interval. SCIC-GDPO achieves the best result

Fig. 2. Median speaker-relative change magnitudes after direction normalization. Down values are sign-flipped so positive values indicate the requested direction; black lines and diamonds denote frozen training-reference magnitudes.

Table 1. RVQ transfer (%). Left: selected single-codebook results with speaker-bootstrap 95% confidence intervals. Right: cumulative transfer over residual-codebook prefixes.

Single-codebook transfer					Cumulative transfer			
Codebook	Pitch Fwd.	Pitch Rev.	Energy Fwd.	Energy Rev.	Attribute	Codebooks	Forward	Reverse
q_0	0.0 [-0.0,0.1]	0.5 [-0.2,1.7]	-0.0 [-0.1,0.0]	-0.0 [-0.1,0.0]	Energy	q_1-q_2	91.0	92.1
q_1	-5.0 [-7.4,-2.8]	18.3 [15.7,21.0]	83.5 [82.7,84.3]	85.3 [84.5,86.1]	Energy	q_1-q_3	94.0	94.7
q_2	-0.1 [-1.6,1.2]	12.7 [10.0,16.1]	6.6 [6.1,7.0]	8.1 [7.7,8.6]	Pitch	q_1-q_4	52.9	68.1
q_3	3.7 [2.6,4.7]	10.2 [7.7,12.9]	2.5 [2.2,2.8]	3.1 [2.7,3.5]	Pitch	q_1-q_6	83.4	88.7
q_4	2.1 [1.4,2.9]	10.2 [7.3,13.0]	1.6 [1.3,2.0]	1.9 [1.6,2.1]	Pitch	q_1-q_8	91.0	96.5
q_5	0.8 [0.2,1.2]	2.9 [-0.9,5.5]	1.0 [0.8,1.2]	1.2 [0.9,1.5]	Pitch	q_1-q_{10}	95.4	99.6

Table 2. Control and quality results. Pitch, Energy, Speed, Pause ACC, and CER are percentages; SIM is cosine similarity, and mean Pause durations are in seconds.

Model	Pitch	Energy	Speed	Pause ACC				Mean Pause			CER↓	SIM↑
				L1	L2	L3	Macro	L1	L2	L3		
Instruction SFT	82.83	85.86	90.89	92.41	92.55	88.81	91.26	0.615	0.863	1.110	1.68	0.8721
SCIC-SFT	90.14	96.39	91.40	94.34	92.79	88.65	91.93	0.618	0.856	1.101	1.63	0.8719
SCIC-GDPO	92.48	97.16	93.86	95.82	95.90	93.68	95.13	0.635	0.876	1.136	1.64	0.8718

at all three levels, and the mean detected durations of all systems lie inside their corresponding target intervals.

On 200 long-form texts, HMOS increases from 3.244 for Zero-Shot and 3.504 for SFT without instructions to 4.042 with paragraph-level instructions, indicating a clearer expressive hierarchy for the complete system.

The control-magnitude results further show that the control-accuracy gains correspond to stronger direction-normalized changes in each attribute’s native domain. Relative to SCIC-SFT, SCIC-GDPO increases the median change magnitude for both directions of Pitch, Energy, and Speed while remaining below the frozen training references.

3.3. Temporal and codebook-axis ablations

Replacing the soft Router with a binary Router reduces Pitch accuracy and increases Boundary MAE from 295 to 375 ms, supporting graded temporal activation. Removing Tag-Specific Codebook Weighting lowers Pitch and Energy accuracy, while its 292-ms Boundary MAE remains close to SCIC-SFT. These results indicate that the Temporal Instruction Router primarily controls instruction scope, whereas Tag-Specific Codebook Weighting mainly controls

Table 3. Ablations: control-direction accuracy (%) and Router Boundary MAE.

Variant	Pitch	Energy	MAE↓
SCIC-SFT	90.14	96.39	295 ms
w/ Hard Router	88.41	96.44	375 ms
w/o Tag-Specific Codebook Weighting	89.43	94.90	292 ms

attribute allocation across residual predictions.

4. CONCLUSIONS

We introduced SCIC for speaker-relative inline prosody control. RVQ Codebook Diagnosis shows that Energy concentrates in early residual codebooks whereas Pitch requires a deeper prefix, motivating temporal routing and tag-specific codebook weighting. Multi-reward GDPO improves Pitch, Energy, Speed, and Pause control while maintaining comparable intelligibility and speaker similarity. Long-form listening indicates a clearer paragraph-level expressive hierarchy for the complete instruction-conditioned system.
