ABSTRACT

Textual skills provide reusable guidance for large language model agents, but existing approaches often rely on manually curated skill banks or reinforcement learning with indirect and delayed feedback. We introduce SkillFM (**S**kill **F**low **M**atching), a generative framework that synthesizes task-conditioned textual skills directly without test-time skill retrieval. Our framework combines a codec for encoding and reconstructing textual skills in a continuous latent space with a conditional flow model trained using improved MeanFlow. At inference time, the learned velocity field enables single-step latent sampling, and an LLM-based decoder converts the sampled representation into textual guidance for a frozen downstream agent. We evaluate the framework on embodied tasks, question answering, and web shopping. On ALFWorld and Search-QA, our method achieves the best overall performance among the compared vector-based skill approaches. Our analyses further demonstrate that latent skill generation is an effective alternative to retrieval-based skill augmentation. Our code and training skill libraries are available at <https://github.com/lulushang999/SkillFM>.

1 INTRODUCTION

Large language model (LLM) agents are increasingly applied across diverse domains and have made substantial progress in reasoning, embodied interaction, and web navigation (Yao et al., 2023; Wang et al., 2023; Gur et al., 2024). As their capabilities grow, external skills remain useful for specialized tasks. Recent work has increasingly focused on how agents can acquire reusable skill banks through interaction with their environments. These studies show that accumulating and reusing skills can improve overall agent performance (Zhao et al., 2024; Xia et al., 2026).

A common design for skill-based self-evolution involves three components: retrieval, execution, and summarization. A retriever selects relevant skills, an executor uses them to interact with the environment, and a summarizer turns the resulting trajectories into new or revised skills (Xia et al., 2026; Ouyang et al., 2026). Their cooperation allows experience to accumulate, but also introduces the need for accurate retrieval and skill-update mechanisms. The system must still determine which guidance fits the current task and how earlier skill updates contribute to later success (Tu et al., 2026; Zhang et al., 2026b).

The usefulness of a skill update is not always evident when it is added to the bank. It may only be assessed on later tasks, where several retrieved skills may be used together. The resulting feedback is delayed and indirect, making it difficult to determine which skills should be retained, revised, or discarded (Ouyang et al., 2026; Zhang et al., 2026b). At the same time, a growing bank can make relevant procedures harder to distinguish from similar but redundant or misleading entries (Song & Wei, 2026; Goulart et al., 2026). Utility estimation (Tu et al., 2026), retrieval (Goulart et al., 2026), and pruning (Li et al., 2026) help keep this accumulated experience usable, but require the system to maintain both the skills and the rules for selecting them. When bank updates are learned together with the agent, training must also coordinate policy optimization, skill evaluation, and bank maintenance (Tu et al., 2026).

*Equal contribution.

†Corresponding author.

Figure 1: **Motivation for SkillFM.** (a) External skill reuse requires retrieval and bank maintenance, with ambiguous matches and delayed feedback. (b) SkillFM learns from a skill bank offline and generates readable guidance through one-step latent sampling and decoding, supporting reuse across frozen actors without test-time bank lookup.

One way to reduce reliance on external skill retrieval is to internalize skills. Skill0 transfers procedural knowledge into the execution policy by gradually withdrawing skill context during reinforcement learning (Lu et al., 2026). LatentSkill instead compiles textual skill descriptions into modular LoRA adapters (Yu et al., 2026). This retains skills as separately usable modules, but still requires an appropriate description as input. These approaches motivate a further step: learning to generate the skill a task needs. We use a continuous latent representation to model skills themselves and internalize the mapping from tasks to skills in a generator, while keeping the downstream actor frozen.

We introduce SkillFM (**Skill Flow Matching**), a framework that generates skills conditioned on the task. A textual skill codec first learns to encode procedures into latent vectors and reconstruct them as readable guidance. With the codec fixed, flow matching learns a conditional velocity field from the encoded skills in the bank, internalizing their procedural knowledge in the generator (Lipman et al., 2023). We train this field using improved MeanFlow (Geng et al., 2026). Given a new query, single-step latent sampling produces a skill code from Gaussian noise, and an LLM-based decoder turns the implicit skill into textual guidance for the actor. This replaces test-time skill retrieval with generation through a decodable latent space.

The skill bank serves as a source of training examples; it is no longer searched during execution. Task-skill pairs supervise the generator directly, without a separate reinforcement learning policy for library-editing actions. At deployment, the generator produces guidance without scoring or retrieving individual bank entries. The output remains readable, and its textual interface allows the same generator to guide different actors without changing their parameters.

We evaluate SkillFM on ALFWorld, Search-QA, and WebShop. On ALFWorld, it achieves 82.14% success on seen tasks and 84.33% on unseen tasks (83.21% overall), improving over the reported LatentSkill results by approximately 7.8 and 14.9 percentage points, respectively. We probe skill internalization by directly fine-tuning the LLM decoder to generate skills. Its substantially lower performance supports learning the task-to-skill mapping through conditional flow matching, with the decoder reconstructing readable skills. With 25% irrelevant skills in the bank, SkillFM also outperforms embedding-based retrieval from the same bank across all three domains, highlighting the advantage of learned skill generation when accumulated skills are imperfect.

Our contributions are:

- We introduce SkillFM, which combines a reconstructable skill codec with improved MeanFlow for single-step latent skill generation.
- We demonstrate superior performance across multiple datasets and greater portability across downstream actors than other skill internalization approaches.

- We analyze the necessity of introducing latent flow and demonstrate that our method outperforms skill retrieval under noisy skill-bank conditions.

2 RELATED WORK

Skill-based agent self-evolution. Skill-based self-evolution turns interaction experience into reusable procedures that guide subsequent decisions (Wang et al., 2023; Zhao et al., 2024). Sustaining this process requires deciding what to retain, when to retrieve it, and how to revise it as failures emerge. Existing systems couple policy learning with recursive skill updates (Xia et al., 2026), train dedicated curators with composite rewards (Ouyang et al., 2026), or alternate controller optimization with skill-bank refinement (Zhang et al., 2026a). Even with frozen executors, reliable evolution involves trajectory attribution, candidate verification, regression checks, and pruning (Mi et al., 2026; Ma et al., 2026). Thus, the benefits of accumulated experience depend on coordinating acquisition, selection, and maintenance through specialized training and update rules. This motivates learning task-conditioned skill generation without a separate test-time bank-management loop.

Skill internalization. Implicit representations replace explicit reasoning tokens with recurrent hidden states (Hao et al., 2024) or vocabulary-weighted soft tokens (Zeng et al., 2025; Deng et al., 2025; 2026). For reusable skills, internalization instead absorbs guidance into policies through curriculum RL (Lu et al., 2026), distills skill-conditioned behavior into adapters (Zhang & Qi, 2026), or compiles skill descriptions into weights (Yu et al., 2026; Zhao et al., 2026). These approaches reduce repeated context overhead but couple the learned skill representation to an execution backbone. Recent work combines parameterized skills with verification-driven revision and continual accumulation (Zhao et al., 2026); transferring the resulting knowledge directly across heterogeneous executors remains a distinct challenge. We learn a decodable skill space and a task-conditioned generator, retaining a textual interface for reuse across frozen executors.

3 METHOD

SkillFM generates a textual skill for a task and supplies it to a frozen executor. The condition c contains the task type and original instruction or question; the skill sequence $s = (s_1, \dots, s_L)$ specifies applicability and execution steps, including a terminator. We first construct a fixed bank of (c, s) pairs, train a skill codec, and then learn a conditional flow over its latent space (Figure 2).

3.1 SKILL COLLECTION

We build the skill bank through iterative execution and summarization on training tasks. The executor collects interaction trajectories, and the summarizer distills reusable procedures from successful attempts. The accumulated skills guide subsequent rounds of execution; collection stops when the success rate no longer improves. We retain successful skills, remove near-duplicates using cosine similarity, and clean the summaries to form fixed (c, s) training pairs. ALFWorld pairs come from training chains, while the QA and shopping banks also include authored or revised skills. The resulting bank trains both the codec and the conditional flow.

3.2 SKILL CODEC

The encoder reads only the skill and produces $z \in \mathbb{R}^d$. A LayerNorm–linear projector P_ψ maps it to K continuous prefix embeddings for the task-conditioned autoregressive decoder D_ω :

$$z = E_\phi(s), \quad \|z\|_2 = 1, \quad p_\omega(s \mid z, c) = \prod_{j=1}^L p_\omega(s_j \mid s_{<j}, P_\psi(z), c). \quad (1)$$

We use $d = 2560$ and $K = 16$. To expose the decoder to nearby codes, the augmentation distribution $\mathcal{A}(z)$ mixes the original code with spherical perturbations $\tilde{z} = \cos(\alpha)z + \sin(\alpha)v$, where v is a

SkillFM: skill construction and training

Figure 2: **Training and inference pipeline.** We train the framework in two stages: the codec learns to encode and decode skills, and conditional flow matching learns to generate latent skills for the decoder. At inference, we reuse the trained flow model and codec to produce textual skill guidance for the agent with one flow evaluation.

random unit vector perpendicular to z . Teacher-forced reconstruction minimizes

$$\mathcal{L}_{\text{codec}} = -\mathbb{E}_{(c,s), \tilde{z} \sim \mathcal{A}(E_\phi(s))} \left[\sum_{j=1}^L \log p_\omega(s_j \mid s_{<j}, P_\psi(\tilde{z}), c) \right]. \quad (2)$$

Only skill tokens and the terminator contribute to the loss; prompt, prefix, and padding positions are masked. We train the projector and encoder/decoder LoRA adapters (Hu et al., 2022), keeping backbone weights frozen. Pooling, adaptation settings, and the perturbation schedule appear in Appendix B.1.

3.3 CONDITIONAL FLOW TRAINING

We freeze the codec and a separate query encoder. The scaled code $x = \sqrt{d} E_\phi(s)$ matches the root-mean-square norm of Gaussian noise, and $q = E_{\text{query}}(c)$ encodes the task condition. Following flow matching (Lipman et al., 2023), we sample $\epsilon \sim \mathcal{N}(0, I_d)$ and $t \sim \mathcal{U}(0, 1)$ and construct

$$x_t = (1 - t)x + t\epsilon. \quad (3)$$

The data endpoint is at $t = 0$ and noise at $t = 1$, with paired velocity $v_{\text{pair}} = \epsilon - x$. A conditional Transformer $u_\theta(x_t, r, t, q)$ predicts interval-average velocity along the conditional marginal flow for $0 \leq r \leq t \leq 1$ (Geng et al., 2025). Its blocks receive the query, time, and interval length $t - r$.

We use the improved MeanFlow objective (Geng et al., 2026). The diagonal evaluation $b_\theta(x_t, t, q) = u_\theta(x_t, t, t, q)$ supplies the instantaneous-velocity estimate without an extra head. At fixed r and q , the derivative correction is $\mathcal{D}_t u_\theta = \partial_t u_\theta + (J_{x_t} u_\theta) b_\theta$, where J_{x_t} is the state Jacobian. The composite prediction is

$$V_\theta = u_\theta(x_t, r, t, q) + (t - r) \text{stopgrad}(\mathcal{D}_t u_\theta), \quad (4)$$

where stopgrad stops gradients through the correction. We optimize only the flow network with

$$\mathcal{L}_{\text{flow}} = \mathbb{E} \left[w \|V_\theta - v_{\text{pair}}\|_2^2 \right], \quad (5)$$

where w is the adaptive regression weight and the expectation covers training pairs, noise, and time intervals. At $r = t$, the correction vanishes, recovering instantaneous flow matching. Appendix A gives the derivation and its assumptions; Appendix B records the architecture and schedules.

3.4 SKILL-GUIDED EXECUTION

For a new task, we compute q and use one flow-network evaluation to predict a skill state:

$$y_1 \sim \mathcal{N}(0, I_d), \quad y_0 = y_1 - u_\theta(y_1, 0, 1, q), \quad \hat{z} = \frac{y_0}{\|y_0\|_2}. \quad (6)$$

Normalization returns the state to the codec’s unit sphere. The frozen decoder greedily generates a skill $\hat{s}$ from $P_\psi(\hat{z})$ and c . The frozen actor then selects $a_k \sim \pi_{\text{actor}}(\cdot \mid c, \hat{s}, h_k)$, where h_k contains interaction history, observations, and available evidence. One skill is generated per task and remains fixed throughout the rollout, with no test-time skill-bank lookup. NFE= 1 counts only the flow-network call; query encoding, skill decoding, and execution are separate computations.

4 EXPERIMENTS

We evaluate SkillFM across embodied interaction, web shopping, and question answering, then analyze executor transfer.

4.1 EXPERIMENTAL SETUP

Benchmarks. We use **ALFWorld** (Shridhar et al., 2021) for household interaction, **WebShop** (Yao et al., 2022) for online shopping, and **Search-QA** for search-based question answering. The Search-QA test subsets are taken from LatentSkill (Yu et al., 2026). We report success rate for ALFWorld and WebShop, mean task score for WebShop, and exact match for Search-QA; aggregation conventions are specified in the corresponding tables.

Baselines. For ALFWorld and Search-QA, we compare Qwen3-8B prompting and retrieval (Wei et al., 2022; Lewis et al., 2020), parameter fine-tuning (Hu et al., 2022), and adapter generation (Liu et al., 2026; Charakorn et al., 2025; Yu et al., 2026), with SkillIOS as an additional ALFWorld reference (Ouyang et al., 2026). For WebShop, we report prompting and memory baselines from Xia et al. (2026), whose backbone is Qwen2.5-7B-Instruct. All baseline scores come from published results. Section 6.1 separately compares embedding-based retrieval under injected noise.

Implementation details. We collect trajectories with Qwen3-8B, summarize successful ones with Qwen3.6-27B, and deduplicate the resulting skills by cosine similarity. The skill used in the alf-world training has a 100% accuracy rate in the training set. The codec uses Qwen3-Embedding-4B encoders and a Qwen3-4B-Instruct-2507 decoder (Zhang et al., 2025; Yang et al., 2025), with 2,560-dimensional codes and 16 prefix embeddings. We first adapt the codec, then freeze it to train a 12-layer conditional DiT. Inference uses one flow evaluation (NFE = 1) and greedy skill decoding; the Qwen3-8B executor remains frozen and uses native thinking mode. For ALFWorld, the trained codec with improved MeanFlow uses the step-10,000 flow checkpoint selected on a holdout from the training domain. Architecture, optimization, decoding settings, and action budgets appear in Appendix B.

4.2 MAIN RESULTS

Tables 1 and 2 report our main result on ALFWorld and Search-QA results with a Qwen3-8B executor. WebShop results appear in Appendix C.1.

Table 1: **Performance on ALFWorld in success rate (%)**. Results are reported on the seen and unseen splits with a per-task breakdown. Step denotes the average number of interaction steps per episode. * denotes results from Yu et al. (2026), version 3. † denotes the three-run means reported by Ouyang et al. (2026) under their evaluation protocol. The best results are highlighted in blue.

Strong performance with a frozen executor. SkillFM achieves the highest reported aggregate ALFWorld and Search-QA scores among the compared vectorized-skill approaches. It reaches 82.14% seen and 84.33% unseen success on ALFWorld (Appendix D), exceeding LatentSkill by approximately 7.8 and 14.9 percentage points, and raises Search-QA micro EM from 35.62% to 39.36%. On WebShop, it achieves 20.00% SR and a score of 55.35, exceeding seven of the eight prompting and memory references in Table 12 (Appendix C.1).

4.3 GENERALIZATION

Transfer across model families. LatentSkill (Yu et al., 2026), SHINE (Liu et al., 2026), and Text-to-LoRA (Charakorn et al., 2025) encode knowledge in backbone-specific LoRA weights, while Skill0 (Lu et al., 2026) internalizes skills in policy parameters. These learned weights are not directly portable across incompatible backbones. Our textual skill interface allows the same generator, trained on skills derived from Qwen3-8B interactions, to guide different frozen executors without retraining. Figure 3 reports gains of 21.53–43.43 percentage points across GPT, Llama, and Mistral actors, demonstrating reuse across model families.

Transfer across model scales. Table 3 further shows consistent improvements with increasing Qwen3 executor size across all three benchmarks. This suggests that more capable actors exploit the same generated guidance more effectively. Additional settings and results appear in Appendix C.2.

Figure 3: **Transfer across ALFWorld actors.** Success rates (%); differences in pp.

5 EXPERIMENTAL ANALYSIS

We analyze the learned components, latent interface, and flow behavior; Section 6 examines skill-bank quantity and quality.

5.1 ABLATION STUDIES

Table 4 compares variants that remove codec adaptation or bypass conditional flow inference. The former uses pretrained encoder and decoder weights; the latter retains the trained decoder and task conditioning but decodes a latent vector without flow inference.

Both ablations reduce performance across all benchmarks. Codec adaptation helps make the latent representation useful for skill generation, although execution results alone do not characterize its geometry. The flow ablation shows that a trained, task-conditioned decoder does not replace conditional code generation.

Decoder-only supervised fine-tuning. This experiment tests whether skills can be internalized directly into the decoder, further examining the role of flow matching. Both decoder-only baselines use the same long prompt. As shown in Table 5, decoder-only fine-tuning performs substantially worse than our full method. These results support a division of roles in which the decoder reconstructs skills and flow matching provides task-conditioned generalization, rather than relying on the decoder alone to internalize skill knowledge.

Table 4: **Component ablations.** SR or aggregate EM (%).

Variant	ALFWorld		WebShop	Search-QA
	Seen	Unseen	SR	EM
Ours	82.14	84.33	20.00	39.36
w/o codec training	10.00	16.42	12.40	31.46
w/o flow	25.00	23.13	16.40	36.93

Table 5: **Decoder-only SFT.** ALFWorld SR (%); Ours uses the full-system configuration in Table 4.

Method	Seen	Unseen	Overall
Qwen3-4B	30.71	43.28	36.86
Qwen3-8B	32.14	50.75	41.24
Ours	82.14	84.33	83.21

5.2 HYPERPARAMETER ANALYSIS

We examine the hyperparameter choices for flow-based skill generation: skill dimension and prefix-token count. Tables 6 and 7 support our choice of 2,560-dimensional skill codes and 16 prefix tokens, which attain or match the highest overall success among the tested settings. Additional diagnostics appear in Appendix F.

Table 6: **Skill-code dimension.** ALFWorld SR (%).

d	Seen	Unseen	Overall
512	77.14	85.07	81.02
1,024	78.57	82.09	80.29
2,560	82.14	84.33	83.21

Table 7: **Prefix length.** ALFWorld SR (%); bold marks column maxima.

K	Seen	Unseen	Overall
4	82.14	83.58	82.85
8	82.14	84.33	83.21
16	82.14	84.33	83.21
32	80.00	85.07	82.48

5.3 FLOW TRAINING ANALYSIS

After training, the velocity field produces distinct directions under different task conditions (Figure 4a). The JVP diagnostic rises early and then generally decreases during training (Figure 4b). These measurements describe task conditioning and optimization dynamics; they do not directly measure decoded-skill quality or execution success. Additional training curves and JVP distributions are provided in Appendices F.4 and F.5.

Figure 4: **Flow training analysis.** (a) PCA of condition-sensitive reverse directions; arrows show task-type means. (b) The logged JVP squared-norm statistic and its binned training trends. Both panels analyze ALFWorld flow training. Additional training and JVP diagnostics appear in Appendices F.4 and F.5.

6 ROBUSTNESS ANALYSIS

6.1 GENERATION VERSUS RETRIEVAL UNDER NOISE

We compare generated and retrieved skill guidance when the skill bank contains 25% irrelevant skills. Our method learns from the contaminated bank during training, while embedding-based retrieval selects guidance from the same bank at test time. Table 8 shows that generated guidance achieves higher performance across ALFWorld, Search-QA, and WebShop under this contamination level.

6.2 TRAINING SCALE AND SKILL QUALITY

On ALFWorld, we vary training-bank size and the fraction of skills derived from successful versus unsuccessful source trajectories, while keeping the evaluation tasks fixed. Table 9 reports the frac-

Table 8: **Generated versus retrieved skill guidance under 25% injected irrelevant skills.** ALFWorld and WebShop report success (%); Search-QA reports EM (%). Δ is generation minus retrieval in percentage points.

Skill source	ALFWorld		Search-QA		WebShop
	Seen	Unseen	Single-hop	Multi-hop	SR
Embedding retrieval	38.57	30.60	42.20	27.45	15.20
Ours	74.29	77.61	45.73	31.82	18.40
Δ (percentage points)	+35.71	+47.01	+3.53	+4.37	+3.20

tion of source trajectories that succeeded. This measures the composition of the training data; it is distinct from injecting irrelevant skills in Section 6.1.

Table 9: **Training-bank size and source-trajectory success.** Cells report success rates (%) on 274 tasks. Column headings indicate the fraction of source trajectories that succeeded. Bold marks the highest success at each training size.

Training examples	100%	75%	50%
500	78.10%	64.96%	63.50%
1,000	79.56%	72.26%	68.98%
3,553	83.21%	78.83%	64.23%

With a high-quality skill bank, halving the number of training skills from 1,000 to 500 causes only a small performance drop. This suggests that skills capture reusable procedural knowledge and that effective generation can be learned from a relatively small bank. When 75% of the source trajectories are successful, performance is lower than with 100% successful source trajectories at all three bank sizes, but the decrease becomes smaller as the bank grows. This suggests that a larger training bank can help when some skills are derived from unsuccessful trajectories.

7 SKILL GENERATION PROCESS

To reveal how the flow transforms latent skills, we explicitly decode intermediate states along a diagnostic trajectory from noise at $t = 1$ to the skill endpoint at $t = 0$ (Appendix E, Figure 5). We hold the task condition and initial noise fixed, normalize a copy of each sampled state, and decode it independently with the frozen codec decoder. This makes the changing skill content visible throughout the flow.

In the illustrated heating task, the decoded skill evolves from malformed, repetitive text into a structured description with increasingly detailed procedural guidance. As the trajectory approaches the endpoint, the skill identifies the correct appliance, specifies the heating action, and separates heating from final placement. Later states also clarify action ordering and completion conditions. The progression thus concerns both a more regular structure and more specific operational details. Although individual trajectories can plateau or regress, this example illustrates how approaching the endpoint can yield more complete guidance. The comparison highlights that a valid output format alone is insufficient: the decoded skill must also preserve task-specific tools, state changes, and action ordering. Inspecting these constraints makes the procedural differences between intermediate states easier to interpret. These intermediate decodings are qualitative diagnostics; the main evaluation still uses one flow evaluation per skill.

8 CONCLUSION

We presented SkillFM, a framework that generates textual skills for frozen LLM agents through conditional latent flow matching. A reconstructable skill codec provides the latent interface, while improved MeanFlow learns task-conditioned skill generation with a single flow evaluation. This design moves skill-bank information into a learned generator and removes test-time skill retrieval. Experiments on ALFWorld, Search-QA, and WebShop demonstrate strong downstream performance.

Our analyses examine the contribution of latent flow beyond decoder-only internalization, sensitivity to skill-bank size and quality, and transfer across downstream actors. Comparisons under noisy skill-bank conditions further show an advantage over embedding-based retrieval. Overall, SkillFM provides a practical alternative to retrieval in agent self-evolution, producing transferable, executable skill guidance that remains effective with imperfect skill banks.

A DERIVATION OF THE IMPROVED MEANFLOW OBJECTIVE

This appendix derives the objective in Section 3.3. The average-velocity formulation follows MeanFlow (Geng et al., 2025), and the learned boundary-field parameterization follows improved MeanFlow (Geng et al., 2026).

A.1 FROM CONDITIONAL FLOW MATCHING TO AVERAGE VELOCITY

For the interpolation in Equation 3, write $v_{\text{pair}} = \epsilon - x$. Standard conditional flow matching fits an instantaneous field by minimizing

$$\mathcal{L}_{\text{FM}}(\theta) = \mathbb{E}_{(c,s),\epsilon,t} \left[\|v_\theta(x_t, t, q) - v_{\text{pair}}\|_2^2 \right]. \quad (7)$$

The conditional mean of the paired velocity defines the marginal field

$$v^*(y, t, q) = \mathbb{E}[v_{\text{pair}} \mid x_t = y, t, q]. \quad (8)$$

Assume finite second moments and sufficient regularity on intervals $0 < r < t \leq 1$ for the ODE and derivatives below to exist. Expressions at $r = 0$ refer to the endpoint limit, assuming that the trajectory limit exists and the velocity is integrable. This qualification accommodates the codec’s spherical data support at $t = 0$. For fixed q , let Y_τ solve $dY_\tau/d\tau = v^*(Y_\tau, \tau, q)$. For $r < t$, define

$$u^*(Y_t, r, t, q) = \frac{1}{t-r} \int_r^t v^*(Y_\tau, \tau, q) d\tau = \frac{Y_t - Y_r}{t-r}. \quad (9)$$

This integral follows the marginal ODE trajectory, which need not coincide with the linear interpolation of an individual data–noise pair.

Average-velocity identity. Holding r and q fixed, differentiate $(t-r)u^*(Y_t, r, t, q) = Y_t - Y_r$ along the same trajectory. The product and chain rules give

$$u^* + (t-r)(\partial_t u^* + J_y u^* v^*) = v^*, \quad (10)$$

where J_y denotes the Jacobian with respect to the state argument. Continuity gives the diagonal boundary value $u^*(y, t, t, q) = v^*(y, t, q)$. This proves the identity used to connect interval-average and instantaneous velocities. It also gives the exact interval update $Y_r = Y_t - (t-r)u^*(Y_t, r, t, q)$ when the exact field is available.

A.2 BOUNDARY PARAMETERIZATION AND LOSS EQUIVALENCE

The network uses its diagonal evaluation $b_\theta(y, t, q) = u_\theta(y, t, t, q)$ to approximate the instantaneous field. Define

$$A_\theta(y, r, t, q) = \partial_t u_\theta(y, r, t, q) + J_y u_\theta(y, r, t, q) b_\theta(y, t, q). \quad (11)$$

With q fixed, this is a Jacobian–vector product for arguments (y, r, t) and tangent $(b_\theta, 0, 1)$. Evaluating A_θ at $y = x_t$ recovers $\mathcal{D}_t u_\theta$ in Section 3.3. When the network is expressed using arguments (y, t, Δ) with $\Delta = t-r$, the equivalent JVP uses tangent $(b_\theta, 1, 1)$: varying t at fixed r changes both time and interval length. This is a change of coordinates for the same derivative, not an additional loss term.

Let $\delta = t-r$. The compound prediction in Equation 4 has an equivalent target-form expression:

$$u_{\text{target}} = \text{stopgrad}[v_{\text{pair}} - \delta A_\theta], \quad (12)$$

$$V_\theta(x_t, r, t, q) = u_\theta(x_t, r, t, q) + \delta \text{stopgrad}[A_\theta]. \quad (13)$$

Because the codec is frozen and the sampled endpoints and times do not depend on θ , their residuals satisfy

$$u_\theta - u_{\text{target}} = V_\theta - v_{\text{pair}}. \quad (14)$$

Both sides also have the same derivative with respect to θ under the stated stop-gradient convention: only the explicit u_θ term is differentiated. Consequently,

$$\mathbb{E} \left[w \|u_\theta - u_{\text{target}}\|_2^2 \right] = \mathbb{E} \left[w \|V_\theta - v_{\text{pair}}\|_2^2 \right], \quad (15)$$

with identical implemented gradients when the same weighting and gradient convention for w are used. Thus the compound-prediction objective in the main text and the target-form objective implement the same improved MeanFlow velocity regression under consistent weighting and gradient conventions. At $r = t$, the derivative correction vanishes and the residual reduces to the standard flow-matching residual for b_θ .

A.3 POPULATION-REGRESSION INTERPRETATION

For this analysis, assume that (r, t) is sampled independently of (x, ϵ, q) , and define $S = (x_t, r, t, q)$. At fixed network parameters and with deterministic network evaluation, V_θ is a function of S alone. Let

$$\xi = v_{\text{pair}} - v^*(x_t, t, q), \quad \mathbb{E}[\xi \mid S] = 0. \quad (16)$$

Expanding $\|V_\theta - v^* - \xi\|_2^2$ and taking conditional expectations makes the cross term zero. Therefore,

$$\mathbb{E} \|V_\theta - v_{\text{pair}}\|_2^2 = \mathbb{E} \|V_\theta - v^*(x_t, t, q)\|_2^2 + \mathbb{E} \|\xi\|_2^2. \quad (17)$$

The final term does not depend on θ . Thus the unweighted population loss measures error against the marginal velocity, up to irreducible conditional variance. The same argument applies to a fixed non-negative weight $w(S)$. It need not apply to a residual-dependent adaptive weight; stopping gradients through such a weight does not remove its statistical dependence on the target noise. Equation 15 remains an algebraic equivalence with the same weights, but this stronger population interpretation requires the stated assumptions.

Role of the predicted tangent. In the original MeanFlow correction, the JVP uses v_{pair} as its state direction. Conditional on S , its derivative term has covariance $J\Sigma J^\top$, where $J = J_y u_\theta(x_t, r, t, q)$ and $\Sigma = \text{Cov}(v_{\text{pair}} \mid S)$. The correction in Equation 11 is instead determined by S . It therefore removes sample-pair variability from the derivative input and permits the regression decomposition above. This does not establish a uniform reduction in the variance of the complete residual or a guarantee of downstream improvement.

The identities concern the exact underlying field and the forward regression objective. Neural approximation, adaptive weighting, and stop-gradient optimization do not themselves imply convergence to that field. The accuracy of the single-evaluation sampler in Equation 6 depends on the learned field; the exact-field identity alone does not guarantee accurate generation.

B TRAINING RECIPES AND EXECUTION DETAILS

We evaluate the same two-stage architecture on ALFWorld, Search-QA, and WebShop, with domain-specific skill banks and training schedules. For Search-QA, we report single-hop and multi-hop training separately. Table 10 summarizes the training recipes, and Table 11 specifies the actor budgets. Appendix F.4 describes the ALFWorld training diagnostics and flow-stage holdout protocol.

Table 10: Domain-specific training recipes for SkillFM.

Domain	Training data	Codec training	Flow training
ALFWorld	3,553 fixed training chains	Encoder/decoder LoRA and projector training	Step 10,000; training-domain holdout selection
Single-hop QA	NQ; 4,000 pairs	Batch 48; 26 epochs	Batch 144 to step 10,000, then 2,304 to step 30,000
Multi-hop QA	2,723 pairs	Batch 48; 24 epochs; selected epoch 9	Batch 192; 30,000 steps; selected step 20,000
WebShop	2,000 pairs	Batch 24; 24 epochs	Batch 144; selected step 30,000

The multi-hop run uses stage-specific 2,451/272 training/holdout partitions. Its codec schedule specifies a minimum of 24 epochs, a maximum of 40, and patience 8; training completes 24 epochs and selects epoch 9. Flow training retains the Adam and EMA states. Six flow candidates are assessed on a fixed stage holdout using format validity, termination, operational or relational proxies, and latent geometry, rather than task EM.

The single-hop flow run resumes from its step-10,000 EMA, rebuilds Adam, and increases the global batch to 2,304 through step 30,000. It does not use the same independent stage holdout as the multi-hop run.

Table 11: Execution budgets for the frozen Qwen3-8B actor.

Domain	Output tokens	Actions	Skill use and evidence retrieval
ALFWorld	8,192	50	One skill; one rollout
Single-hop QA	2,048	4	Top-3 evidence retrieval
Multi-hop QA	8,192	4	Top-3 evidence retrieval; grounded hybrid
WebShop	4,096	30	One skill; one rollout

Token and action limits apply independently.

The main ALFWorld evaluation uses the trained codec with improved MeanFlow (Classic Codec + iMF), a 2,560-dimensional skill code, and one flow-network evaluation (NFE = 1). The step-10,000 flow checkpoint is selected on a holdout from the training domain. The frozen Qwen3-8B executor uses native thinking mode. Success is 115/140 (82.14%) on seen tasks and 113/134 (84.33%) on unseen tasks, totaling 228/274 (83.21%). The average interaction length is 16.59 steps on seen tasks and 15.79 steps on unseen tasks.

The Qwen3-8B actor uses temperature 0.6, top- p 0.95, top- k 20, and min- p 0. The skill decoder uses greedy generation, and QA retrieves from eight FP16 FAISS shards.

B.1 METHOD IMPLEMENTATION DETAILS

Codec backbones and pooling. The skill encoder and the separate frozen query encoder use Qwen3-Embedding-4B, and the skill decoder uses Qwen3-4B-Instruct-2507 (Zhang et al., 2025; Yang et al., 2025). For valid skill-token states $h_1, \dots, h_L$, the skill encoder combines the last state with a short trailing average and then normalizes:

$$\bar{h} = 0.75h_L + \frac{0.25}{m} \sum_{j=L-m+1}^L h_j, \quad m = \min(4, L), \quad (18)$$

$$E_\phi(s) = \bar{h} / \|\bar{h}\|_2 \in \mathbb{R}^{2560}.$$

The prefix projector applies LayerNorm followed by a linear map and reshapes its output into 16 vectors of the decoder embedding dimension.

Codec adaptation. Stage I trains the projector and LoRA adapters (Hu et al., 2022) in the last eight encoder layers and across the decoder layers, while freezing the pretrained backbone weights. Both sets of adapters use rank 16, scaling 32, and dropout 0.05. The learning rates are 2×10^{-6} for the encoder adapters, 10^{-5} for the decoder adapters, and 10^{-4} for the projector.

Latent perturbation. For a unit skill code z , a random unit tangent v and angle α define

$$\tilde{z} = \cos(\alpha)z + \sin(\alpha)v, \quad v^\top z = 0, \quad \|v\|_2 = 1. \quad (19)$$

Orthogonality preserves $\|\tilde{z}\|_2 = 1$.

The norm-preserving perturbation described in Section 3.2 is applied with probability 0.75, using an angular standard deviation of 0.16 radians and a maximum magnitude of 0.35 radians. The perturbation strength is ramped over eight epochs.

Flow architecture and conditioning. The flow network processes the 2,560-dimensional latent state with 12 Transformer layers of width 768 and 12 attention heads. The query q , time t , and interval length $t - r$ condition every block and the output through adaLN-Zero (Peebles & Xie, 2023). Only the flow network is trained in Stage II, with the codec and query encoder frozen and no auxiliary head.

C SUPPLEMENTARY EXPERIMENTAL RESULTS

C.1 WEBSHOP MAIN RESULTS

Table 12 compares our frozen Qwen3-8B executor with the prompting and memory baselines reported by Xia et al. (2026), which use Qwen2.5-7B-Instruct.

Table 12: **Performance on WebShop in success rate (%) and task score.** SR denotes complete success, and Score denotes the mean task reward.

Method	SR↑	Score↑	Method	SR↑	Score↑
ReAct	19.50	46.20	MemP	6.40	25.30
Reflexion	28.80	58.10	SimpleMem	8.59	33.20
Mem0	2.00	23.90	MemRL	9.20	29.50
ExpeL	11.20	30.90	EvolveR	17.60	42.50
Ours				20.00	55.35

C.2 TRANSFER ACROSS EXECUTOR SCALES

Cross-family transfer is reported in Figure 3; the tables below expand the scale comparison in Table 3.

Search-QA comprises Natural Questions (NQ) (Kwiatkowski et al., 2019), TriviaQA (Triv) (Joshi et al., 2017), PopQA (Pop) (Mallen et al., 2023), HotpotQA (Hotp) (Yang et al., 2018), 2Wiki-MultiHopQA (2WK) (Ho et al., 2020), MuSiQue (MuS) (Trivedi et al., 2022), and Bamboogle (Bam) (Press et al., 2023). We use the evaluation subsets selected by Yu et al. (2026).

Table 13: **Search-QA across executor scales.** Scores are EM (%); Avg is the unweighted mean over seven datasets.

Actor	NQ	Triv	Pop	Hotp	2WK	MuS	Bam	Avg
Qwen3-4B	37.4	57.0	40.4	33.2	37.2	11.0	37.6	36.26
Qwen3-8B	38.8	62.0	41.4	38.4	43.2	11.0	44.8	39.94
Qwen3-32B	39.2	66.4	41.8	42.6	46.2	16.0	48.8	43.00

Table 14: **WebShop across executor scales.** SR is success (%) over 500 tasks; Score is mean reward on a 0–100 scale.

Actor	SR (%)	Score
Qwen3-4B	14.60	53.36
Qwen3-8B	20.00	55.35
Qwen3-32B	21.60	51.88

C.3 TRAINING-BANK SIZE AND QUALITY

The source-trajectory success rate is the nominal proportion of successful trajectories used to construct a skill bank. For example, a 75% rate means that 75% of the source trajectories were successful and 25% were unsuccessful; skills are derived from this mixture. This tests the quality of task-related experience, whereas Section 6.1 injects skills from unrelated tasks; the two percentages describe different interventions.

Table 15: **ALFWorld training-bank size and quality.** Success rates (%) on 140 seen and 134 unseen tasks; Overall pools all 274 tasks.

Skills N	Source success	Seen	Unseen	Overall
500	100%	75.00%	81.34%	78.10%
500	75%	58.57%	71.64%	64.96%
500	50%	62.86%	64.18%	63.50%
1,000	100%	76.43%	82.84%	79.56%
1,000	75%	68.57%	76.12%	72.26%
1,000	50%	65.00%	73.13%	68.98%
3,553	100%	82.14%	84.33%	83.21%
3,553	75%	75.71%	82.09%	78.83%
3,553	50%	62.14%	66.42%	64.23%

Bank-composition percentages are nominal.

D ALFWORLD FAILURE ANALYSIS

We analyze the main ALFWorld evaluation of SkillFM with one flow-network evaluation (NFE = 1), using all 140 seen and 134 unseen raw rollouts. All 46 failed episodes exhausted the 50-step budget, and all 46 associated skills decoded successfully. The categories below describe observable execution behavior; they do not isolate a causal fault in the condition embedding, flow model, codec decoder, or executor.

D.1 FAILURE STATISTICS

Table 16: **Observable failure patterns on ALFWorld.** Counts refer to failed episodes. The three acquisition categories partition the failures; the invalid-action row can overlap with them.

Observable pattern	Seen	Unseen
Failed episodes	25/140 (17.86%)	21/134 (15.67%)
Never executed a <code>take</code> action	16	13
Took objects, but only of another category	4	6
Acquired the correct category, but did not finish	5	2
At least one inadmissible action	12	9

Failure to acquire the correct target is the dominant observable bottleneck (20/25 seen and 19/21 unseen failures). Category confusions include `cup/mug`, `cloth/handtowel`, and `knife/butterknife`. After correct acquisition, seen failures include repeatedly moving an already placed first object and failing to inspect an object under a lamp. Both unseen failures in this category are two-object tasks with only one object placed. Repeated visits to previously searched locations also consume the action budget.

D.2 SEEN: UNDOING A COMPLETED PLACEMENT

Goal: put two toiletpaper in drawer. **Task ID:** 27d5362c624c487cd1ae. The supplied skill requires two different instances in the same drawer. Its training route uses `toiletpaper 2` and `toiletpaper 1`, while its fallback explicitly states: “Record the placed object’s instance identifier and never take that first instance again.” The following actions are copied verbatim from the rollout; omitted steps are marked by ellipses.

```
03. take toiletpaper 3 from countertop 2
04. go to drawer 4
05. open drawer 4
06. move toiletpaper 3 to drawer 4
... [searching other locations]
15. go to drawer 4
```

```

16. take toiletpaper 3 from drawer 4
17. move toiletpaper 3 to drawer 4
...
35. take toiletpaper 3 from drawer 4
36. move toiletpaper 3 to drawer 4
...
48. take toiletpaper 3 from drawer 4
49. move toiletpaper 3 to drawer 4
50. go to toiletpaperhanger 1

```

Error and skill analysis. Step 16 retrieves the already placed first object; steps 35 and 48 repeat the same mistake. The environment confirms both its placement at step 6 and its retrieval at step 16. The skill correctly specifies instance tracking and forbids undoing completed requirements, but these textual constraints do not prevent repeated manipulation of the same instance. Its scene-specific route also needs adaptation to the observed object identifiers. This trajectory demonstrates a failure to preserve task progress while applying the skill, rather than evidence that the skill instructed the wrong action; no second distinct instance is placed before timeout.

D.3 UNSEEN: SUBSTITUTING THE WRONG OBJECT CATEGORY

Goal: put a clean knife in countertop. **Task ID:** 486925af43052b83756b. The supplied skill states “Find and take one knife.” It then requires cleaning the same instance with a sinkbasin before placing it on a countertop. Its fallback acquisition command is `take knife <instance> from <source receptacle>`.

```

... [repeated search, with no knife acquired]
24. go to countertop 2
25. take butterknife 1 from countertop 2
26. go to sinkbasin 1
27. clean butterknife 1 with sinkbasin 1
28. go to countertop 2
29. move butterknife 1 to countertop 2
... [continued search; no knife acquired]
50. go to countertop 1

```

Error and skill analysis. Step 25 selects `butterknife 1`, although both the goal and skill specify `knife`. The observation at step 24 lists a `butterknife 1`, and the environment confirms its acquisition, cleaning, and placement. These actions are executable but do not satisfy the target category. The executor follows the skill’s clean-then-place structure while violating its object constraint. Thus, procedural guidance alone does not ensure exact category grounding or effective recovery after an unsuccessful search. Together, the examples show that successful decoding and correct textual constraints are insufficient for reliable execution; the rollouts alone cannot establish which model component caused the deviations.

E SKILL GENERATION PROCESS DETAILS

Diagnostic protocol. We decode six states along a fixed five-step Euler trajectory ($\Delta t = 0.2$) from the ALFWorld checkpoint used for the diagnostic, holding the task condition and initial noise fixed. At each state, only the copy passed to the frozen decoder is unit-normalized. Each snapshot is decoded independently into applicability, high-level guidance, and low-level guidance; the sequence therefore reveals changes in the guidance supported by the latent state, rather than successive edits to one text. This diagnostic trajectory is separate from the one-step inference used in the main evaluation.

From format to executable constraints. Figure 5 follows a heating task. At $t = 1$, the output is malformed and repetitive. A valid structure appears at $t = 0.8$, but the suggested stove procedure remains incorrect. By $t = 0.6$, the skill names the correct microwave yet substitutes opening and waiting for the required state-change operation. At $t = 0.4$, an explicit heat action emerges, but the

skill still treats heating as satisfying the final placement goal. Thus, recovering the expected format and tool does not by itself recover a valid procedure.

Action ordering and termination. At $t = 0.2$, the guidance distinguishes the two subgoals: heating changes the egg’s state and leaves it held; a separate move places it on the dining table. The endpoint retains this protocol and explicitly requires the state-change action before final placement. The meaningful change is therefore the recovery of operational constraints and the condition for completion, beyond a more fluent description. These distinctions connect the high-level plan to the low-level actions the executor must perform.

Scope of the observation. The other fixed cases include plateaus and regressions; the cooling case recovers its correct operation only at the endpoint. Refinement is therefore not uniformly monotonic. The four cases use cached noise from the flow checkpoint-selection holdout, which may have been seen by the codec; the heating case was selected for display after inspecting them. Because the decoder receives the task at every state, initial task relevance alone does not establish useful latent information. These observations concern decoded guidance: concrete scene routes and environment success were not evaluated.

Task: heat some egg and put it in diningtable.

$t = 1.0$ <i>Invalid format</i> <pre>{ "when_to_use": "When the egg is cold and needs to be heated, use this skill.", "high_level_guidance": "Heat the egg using a stove or microwave until it reaches the desired temperature ...", "low_level_guidance": "Locate the egg, place it on the stove or microwave, set the heat level, wait for heating to complete ..." }</pre> <i>[object repeats; truncated]</i> Repeated output; wrong heating recipe	$t = 0.8$ <i>Valid format</i> <pre>{ "when_to_use": "When the egg is cold and the stove is off, heat the egg on the stove.", "high_level_guidance": "Heat the egg on the stove until it is hot, then place it on the dining table.", "low_level_guidance": "Pick up the egg, go to the stove, place the egg on the stove, wait until the egg is hot ..." }</pre> Valid structure; wrong tool	$t = 0.6$ <i>Valid format</i> <pre>{ "when_to_use": "Use when a heatable egg is visible and a diningtable receptacle is visible ...", "high_level_guidance": "Find an egg, heat it with the microwave, then carry it to the diningtable. ...", "low_level_guidance": "Go to microwave. When the microwave is not in use, open it. ... Wait for the egg to be heated. ..." }</pre> Correct tool; incomplete procedure
$t = 0.4$ <i>Valid format</i> <pre>{ "when_to_use": "... requiring one egg to be hot and then placed in or on a diningtable; the required ALFWorld tool is microwave. ...", "high_level_guidance": "... That macro moves the egg into the hot state and automatically satisfies the goal's placement requirement. No further movement or transformation is needed. ...", "low_level_guidance": "... STEP 4: 'heat egg with microwave' ... follow it exactly as written and stop after step 4's successful macro. ..." }</pre> Heat action; premature completion	$t = 0.2$ <i>Valid format</i> <pre>{ "when_to_use": "... requiring one egg to be hot and then placed in or on a diningtable; the required ALFWorld tool is microwave. ...", "high_level_guidance": "... That macro sets the target to hot and leaves it held. Keep the same target instance, carry it to a diningtable, and move it there. ...", "low_level_guidance": "... STEP 4: 'heat egg 1 with microwave 1' STEP 5: 'go to diningtable 1' STEP 6: 'move egg 1 to diningtable 1' ..." }</pre> Separate heating and placement	$t = 0.0$ <i>Valid format</i> <pre>{ "when_to_use": "... requiring one egg to be hot and then placed in or on a diningtable; the required ALFWorld tool is microwave. ...", "high_level_guidance": "... That macro sets the target to hot and leaves it held. Keep the same target instance, carry it to a diningtable, and move it there. ...", "low_level_guidance": "... Use only microwave, not stove, stoveburner, oven, or toaster. ... The state-change macro must precede this final move even when the tool and destination have the same class. ..." }</pre> Required protocol retained

Figure 5: **Skill content along a five-step diagnostic flow trajectory.** Cards show the original three fields from $t = 1$ to $t = 0$. Quotes are verbatim excerpts; ... marks omissions. Red indicates procedural errors and green recovered constraints. At $t = 1$, the excerpt comes from a malformed, token-truncated output. This task-conditioned diagnostic measures decoded skill content rather than environment success.

F TRAINING AND HYPERPARAMETER ANALYSIS

F.1 LATENT DIMENSION AND DOWNSTREAM SUCCESS

Table 6 compares the three skill dimensions evaluated in Section 5.2; we select $d = 2560$ based on overall success.

The 2,560-dimensional setting achieves the highest seen and overall success among the tested dimensions, while the 512-dimensional setting has the highest unseen success. These results support the selected dimension without implying a monotonic benefit from increasing dimension.

F.2 PREFIX LENGTH AND DOWNSTREAM SUCCESS

Table 7 reports results for different numbers of continuous prefix embeddings supplied to the skill decoder. These are soft embeddings produced by the projector, rather than additional discrete skill-text tokens.

Pooled success varies within a 0.73-point range across the four prefix lengths. The $K = 8$ and $K = 16$ settings tie for the highest pooled success at 83.21%, while $K = 4$, $K = 8$, and $K = 16$ tie for the highest seen success. The $K = 32$ setting achieves the highest unseen success but lower seen and pooled success. We use $K = 16$ in the main method; increasing the prefix length further does not improve overall success.

F.3 PREFIX LENGTH AND RECONSTRUCTION

We vary the number of continuous prefix embeddings while freezing the skill encoder and optimizing the projector and a fresh decoder LoRA adapter. This diagnostic uses 2,776 training and 305 validation examples, global batch size 12, and 232 updates per epoch. Noise strength ramps through epoch 8.

Table 17: **Training reconstruction cross-entropy by prefix length.** Values are epoch means; bold marks the lowest loss per epoch.

Prefix length K	Epoch 1	Epoch 8	Epoch 16	Epoch 24
4	1.631252	0.007894	0.004181	0.001952
8	1.516875	0.008462	0.004854	0.002112
16	1.231258	0.007750	0.003986	0.001594
32	1.328236	0.007550	0.003797	0.001281

Training loss drops by more than 99% between epochs 1 and 8 for every prefix length. Subsequent optimization further lowers training loss, with $K = 32$ reaching the lowest value at epochs 8, 16, and 24. However, validation curves flatten and later rise, suggesting that continued fitting of the training set does not translate into better held-out reconstruction. The close clean and full-noise validation curves indicate limited sensitivity to the displayed latent perturbation setting; this is distinct from contamination of the training skill bank in Appendix C.3. The lowest late-epoch training loss occurs at $K = 32$, whereas the highest downstream success in Table 7 is shared by $K = 8$ and $K = 16$. These observations underscore that training reconstruction loss is not a substitute for downstream evaluation.

Figure 6: Latent-to-prefix reconstruction on ALFWorld. The supplied learning curves show training cross-entropy and clean/full-noise validation cross-entropy on a logarithmic scale. Shading marks the noise ramp through epoch 8, and stars mark selected checkpoints. The plot’s L denotes prefix length, written as K in this paper. These are reconstruction diagnostics, not downstream success curves.

F.4 FLOW-TRAINING DIAGNOSTICS

We analyze ALFWorld iMF training to examine optimization dynamics and checkpoint selection. The training diagnostics cover 30,000 optimizer updates with global batch size 192. Of 3,553 training bindings, 3,171 enter flow-gradient training and 382 form a fixed flow-stage holdout spanning 99 semantic conditions and six task types. The holdout is independent of flow-gradient updates, but is not established as unseen by the entire codec–flow pipeline. Its EMA checkpoints are evaluated with one flow-network call ($\text{NFE} = 1$), consistent with the main sampler.

Training loss and endpoint geometry. Figure 7 contrasts the training objective with holdout endpoint-set errors. For each semantic condition, we compute nearest-neighbor squared geodesic distances in both generated-to-reference and reference-to-generated directions. Their symmetric average forms the Chamfer criterion. Scores are macro-averaged over conditions within each task type and then over task types. The forward direction measures proximity to reference codes; the reverse direction additionally reflects coverage of the reference set in latent space.

Figure 7: **ALFWorld flow-training diagnostics.** Left: training-loss medians and 10th–90th percentiles within 200-update bins from one run. Right: condition-matched, macro-averaged EMA endpoint errors on the flow-stage holdout; the star marks the selected checkpoint.

Table 18: **Recorded EMA checkpoints and endpoint diagnostics.** Loss is the mean over the preceding 1,000 optimizer updates. Chamfer is in rad^2 ; angular statistics are in radians. Bold marks the lowest loss or Chamfer among the three checkpoints.

Updates	Training loss	Holdout Chamfer	Mean angle	Angle P95
10,000 (selected)	5.670	0.014282	0.09467	0.28164
20,000	4.315	0.014569	0.09415	0.28416
30,000	3.827	0.014731	0.09498	0.28319

Nearest-neighbor angles are macro-averaged by condition and task type; P95 pools generated endpoints.

From 10k to 30k updates, the preceding-window training loss falls by 32.50%, from 5.670 to 3.827, while holdout Chamfer increases by 3.14%, from 0.014282 to 0.014731. Thus, minimizing the training objective further does not improve the recorded endpoint geometry. The 10k checkpoint has the lowest holdout Chamfer among the three evaluated checkpoints, supporting its selection over the final checkpoint. These are different objectives and weight estimates, rather than a conventional train–validation loss gap; the single run does not establish significant overfitting or a decline in environment success.

As shown in Table 18, the generated-to-reference mean angle remains between 0.09415 and 0.09498 radians, and its pooled P95 lies between 0.28164 and 0.28416 radians. Neither shows sustained improvement after 10k. These angular measurements characterize latent geometry and do not measure decoded-skill correctness, textual diversity, or task success.

F.5 DIRECTIONAL-DERIVATIVE DYNAMICS

We also inspect the JVP used by the improved MeanFlow correction in the same training run. Let $D_{k,a,i}$ denote the state-and-time directional derivative of the average-velocity prediction for sample i on worker a at update k , along the predicted boundary velocity with r and q fixed (Section 3.3). The recorded statistic is

$$J_k = \frac{1}{R} \sum_{a=1}^R \sum_i \omega_{k,a,i} \|D_{k,a,i}\|_2^2, \quad (20)$$

where $R = 6$ and $\omega_{k,a,i}$ are the original sampler weights. This preserves the logged reduction: a weighted sum within each worker followed by an average across workers, with the norm summed over all latent coordinates. It is not a parameter-gradient norm. Moreover, J_k omits the squared interval $(t - r)^2$ and therefore does not measure the actual target-correction magnitude. At $r = t$, that correction vanishes even if the directional derivative is nonzero.

Figure 8: **Directional-derivative diagnostics during IMF training.** Left: per-update J_k (faint trace), 200-update means and medians, and within-bin 10th–90th percentiles. Right: the 1,000 updates preceding each evaluated checkpoint; boxes show the interquartile range, whiskers the 10th–90th percentiles, horizontal lines medians, diamonds means, and dots values beyond the whiskers, on a logarithmic axis. Each observation is a weighted minibatch aggregate, not an individual-example derivative or an independent training run.

The typical derivative magnitude rises early and then decreases (Figure 8). Over the 1,000 updates preceding 10k, 20k, and 30k, its means are 371.03, 196.76, and 186.02, and its medians are 297.56, 88.87, and 77.42. The mean falls by 49.86% between the first and last windows, but remains well above the median, indicating a persistent right tail. The corresponding P90 values are 754.03, 516.42, and 524.27, so even this tail statistic does not decrease monotonically. All 30,000 logged values are finite; the largest is 2722.71 at update 24,117, confirming that occasional late spikes remain.

The diagnostic run uses an off-diagonal sampling probability of 0.25. Because J_k aggregates unscaled derivatives, it describes directional-derivative magnitude rather than the interval-scaled target correction. These measurements describe the directional derivatives encountered during one training run; without controlled ablations they do not establish a causal stabilization effect or a global smoothness guarantee. In particular, the decline in typical JVP magnitude does not coincide with improved holdout Chamfer in Table 18.

F.6 SCOPE OF THE HYPERPARAMETER COMPARISONS

The analyses above cover latent dimension, prefix length, and flow-training dynamics. Section 5.3 compares condition-dependent directions with fixed noise, and Section 7 examines intermediate decoded skills. Appendix B gives the domain-specific training recipes.

G EVALUATION SCOPE

The multi-hop evaluation policy is developed and tuned without using test-set information and is fixed before final evaluation.

H CONDENSED PROMPT TEMPLATES

H.1 ALFWORLD

ACTOR: SYSTEM MESSAGE

```
You are an expert agent operating in the ALFRED Embodied Environment.  
Think carefully, then choose exactly one action from the supplied  
candidate list and follow the required response format exactly.
```

ACTOR: USER MESSAGE

Think privately about which observed actions and state transitions made  
the  
trajectory succeed. Preserve the necessary ordering, prerequisites,  
progress  
checks, and completion evidence. Generalize away incidental scene  
identifiers  
without inventing actions or failure lessons that are not supported by  
this  
successful trajectory.
```

Return exactly one JSON object:

```
{
  "when_to_use": "Describe the goal pattern, observable prerequisites,
and decision point that should trigger this skill.",
  "high_level_guidance": "Describe the ordered subgoals, prerequisites,
state transitions, and completion checks.",
  "low_level_guidance": "Give concrete action-selection and
verification rules grounded in trajectory evidence while generalizing
away scene-specific entity identifiers."
}
```

SUMMARIZER: UNSUCCESSFUL TRAJECTORY

You revise the next executable ALFWorld skill after one failed interaction trajectory.

Task type: {TASK_TYPE}
Goal: {TASK_GOAL}

Skill used in the failed attempt:
{CURRENT_SKILL}

Failed trajectory:
{TRAJECTORY}

Failure status:
{FAILURE_REASON}

Think privately about the first unsupported assumption, missing prerequisite, bad ordering decision, loop, or absent verification rule. Produce a replacement skill for the next rollout. It must materially improve on the executed skill and generalize away incidental scene identifiers.

Return exactly one JSON object:

```
{
  "when_to_use": "Describe the goal pattern, observable prerequisites,
and decision point that should trigger this skill.",
  "high_level_guidance": "Describe the ordered subgoals, prerequisites,
state transitions, and completion checks.",
  "low_level_guidance": "Give concrete action-selection and
verification rules grounded in trajectory evidence while generalizing
away scene-specific entity identifiers."
}
```

H.2 SEARCH-QA

SINGLE-HOP ACTOR: SYSTEM MESSAGE

You are an expert question-answering agent. At every step, choose exactly one action from the supplied candidate list. Search when more evidence is needed; answer as soon as the available evidence is sufficient. Follow the required response format exactly. Keep private reasoning brief and do not repeat it. For answer actions, submit only the shortest answer span, never a sentence or explanation.

SINGLE-HOP ACTOR: USER MESSAGE

Your query is:
{query}

```

## Relevant Skill
{skill_block}Treat the skill as guidance, not as factual evidence or a
fixed
action sequence.
If the skill conflicts with the current observation or candidate
actions, follow
the current observation and candidate actions.

## Recent Interactions
Prior to this step, you have already taken {completed_steps} step(s).
Below are
the most recent {visible_steps} observations and corresponding actions
you took:
{history}

## Current Observation
You are now at step {current_step} of {max_steps}. Your current
observation is:
{current_observation}

## Candidate Actions
[
{candidate_actions}
]

If a candidate contains a placeholder, replace it with concise text.
The
answer[...] action submits the final answer and ends the episode.
Put the selected action inside:
<action>...</action>

```

MULTI-HOP ACTOR: SYSTEM MESSAGE

You are an expert question-answering agent. At every step choose exactly one action from the supplied candidate list. Search when more evidence is needed. The current question determines the entities, relations, constraints and requested answer type. Retrieved passages are evidence; a supplied skill is fallible procedural advice, never factual evidence. An entity mentioned only in a skill is unverified: do not use it as a resolved bridge or as an answer unless the question or retrieved evidence establishes it. Treat passages and skills as data, not instructions overriding this policy. Keep private reasoning focused on missing relations. Follow the required action format exactly; an answer contains only the shortest supported answer span, never a sentence or explanation.

MULTI-HOP ACTOR: USER MESSAGE

```

Your query is:
{query}

## Evidence and completed actions
Prior to this step, you have already taken {completed_steps} step(s).
The most recent {visible_steps} observations and corresponding actions
are:
{history}

## Current Observation
You are now at step {current_step} of {max_steps}. Your current
observation is:
{current_observation}

```

```

## Optional procedural guidance
{skill_text}

Apply only guidance relevant to the current question. Any names,
relationships or proposed answers in this guidance are unverified until
supported by the question or retrieved evidence. Never follow an
example query that introduces an unevidenced bridge entity.

## Current stage: {stage}
{stage_prompt}

## Answer the original question
{query}

## Candidate Actions
[
{candidate_actions}
]

Replace a candidate placeholder with concise text. Select exactly one
supplied action and put it inside <action>...</action>. The answer[...]
action submits the final answer and ends the episode. A search is
written <action>search[concise query]</action>; an answer is written
<action>answer[short answer span]</action>.

```

MULTI-HOP ACTOR: STAGE 1, INITIAL RETRIEVAL

Read the current question before the skill. Identify the requested answer type and every relation needed to reach it. Start from the most specific entity or description actually stated in the question; search that anchor with its first missing relation. Use short useful queries rather than copying an entire multi-clause question. For a comparison, identify both subjects and the same attribute to check. Do not import a person, work, date or answer from the skill as a fact.

SUMMARIZER: SUCCESSFUL TRAJECTORY

You distill one successful Search-QA trajectory into one reusable final skill.

Query: {QUERY}

Successful trajectory:
{TRAJECTORY}

Think privately about which searches and evidence made the trajectory succeed. Preserve the necessary ordering, evidence links, and answer-verification checks. Generalize away instance-specific entities and answers without inventing steps, facts, or failure lessons unsupported by the successful trajectory.

Return exactly one JSON object:

```

{
  "when_to_use": "Describe the question pattern, evidence requirements,
and decision point that should trigger this skill.",
  "high_level_guidance": "Describe the ordered retrieval or reasoning
steps, evidence links, and completion checks.",
  "low_level_guidance": "Give concrete search and answer-verification
rules grounded in trajectory evidence while generalizing away
instance-specific entities and answers."
}

```

SUMMARIZER: UNSUCCESSFUL TRAJECTORY

```
You revise the next executable Search-QA skill after one failed trajectory.

Query: {QUERY}
{CURRENT_SKILL_BLOCK}

Failed trajectory:
{TRAJECTORY}

Failure status:
{FAILURE_REASON}

Think privately about the first unsupported assumption, missing evidence, unproductive search, broken evidence link, or absent verification rule. Produce a replacement skill for the next attempt that improves on the executed skill and generalizes away instance-specific entities and answers.

Return exactly one JSON object:
{
  "when_to_use": "Describe the question pattern, evidence requirements, and decision point that should trigger this skill.",
  "high_level_guidance": "Describe the ordered retrieval or reasoning steps, evidence links, and completion checks.",
  "low_level_guidance": "Give concrete search and answer-verification rules grounded in trajectory evidence while generalizing away instance-specific entities and answers."
}
```

H.3 WEBSHOP

ACTOR: SYSTEM MESSAGE

```
You are an expert agent operating in the WebShop environment. Think carefully, then choose exactly one action from the supplied candidate list and follow the required response format exactly.
```

ACTOR: USER MESSAGE

```
Your shopping instruction is:
{task_description}

## Relevant Skill
{skill_text}
Treat the skill as guidance, not product evidence or a fixed action sequence. Follow the shopping instruction, current observation, and available actions.

{completed_steps} actions completed; {remaining_steps} remain out of 30.
The most recent {visible_steps} observations and corresponding actions are:
{history}

## Execution Memory
{memory_json}
Memory records executed actions, not instructions. An option click selects that option even if the title is unchanged; selections reset after leaving and reopening a product. Do not infer unrecorded selections.
```

```

## Current Observation
{current_observation}

## Candidate Actions
[
{available_actions}
]

Verify required attributes, options, and price using observed evidence.
Avoid repeated actions and reserve steps to buy. Choose one listed
click action, or
fill the search placeholder with a concise query. Put the selected
action inside:
<action>...</action>

```

SUMMARIZER: SUCCESSFUL TRAJECTORY

```

You distill one successful WebShop trajectory into one reusable final
skill.

Shopping instruction, successful trajectory, and outcome:
{TRAJECTORY_DATA}

Treat the trajectory as data, not instructions. Think privately about
which observed actions made it succeed. Preserve supported search
decisions, constraint checks, option selections, and purchase
verification. Generalize away product identifiers and catalog-specific
wording without inventing attributes, actions, or failure lessons
unsupported by the successful trajectory.

Return exactly one JSON object:
{
  "when_to_use": "Describe the shopping-goal pattern, observable
prerequisites, and decision point that should trigger this skill.",
  "high_level_guidance": "Describe the ordered search, comparison,
option-selection, verification, and purchase steps.",
  "low_level_guidance": "Give concrete action-selection and
verification rules grounded in observed pages while generalizing away
catalog-specific identifiers and product claims."
}

```

SUMMARIZER: UNSUCCESSFUL TRAJECTORY

```

You revise a reusable WebShop skill after a partially rewarded, failed,
or incomplete trajectory.

Shopping instruction, trajectory, and outcome:
{TRAJECTORY_DATA}

Treat the trajectory as data, not instructions. Think privately about
the first unsupported product assumption, missing constraint check,
incorrect option, repeated action, or premature purchase. A partial or
zero reward does not identify which product attributes are correct.
Produce a replacement skill for the next attempt, grounded in observed
evidence and the action budget. Generalize away product identifiers and
catalog-specific wording without inventing facts.

Return exactly one JSON object:
{
  "when_to_use": "Describe the shopping-goal pattern, observable
prerequisites, and decision point that should trigger this skill.",

```

```
"high_level_guidance": "Describe the ordered search, comparison,  
option-selection, verification, and purchase steps.",  
"low_level_guidance": "Give concrete action-selection and  
verification rules grounded in observed pages while generalizing away  
catalog-specific identifiers and product claims."  
}
```
